# Motivation

- Warm dark matter (WDM) provides an interesting alternative to cold dark matter (CDM) candidates since it can be tested with astrophysical observations on small scales where the CDM model is challenged.
- WDM has a non-negligible velocity dispersion which dampens the small scale fluctuation spectrum and sets a phase space limit to cosmic structures.
- More recently we have seen renewed interest in warm dark matter since a candidate may occur naturally within extensions to the standard model of particle physics.
- The sterile neutrino can explain some key physical phenomena including neutrino oscillations, the dark matter and the baryon asymmetry of the universe.

# The effects of free streaming on warm dark matter haloes: a test of the Gunn-Tremaine limit

## ABSTRACT

The free streaming of warm dark matter particles dampens the fluctuation spectrum, flattening the mass function of haloes and imprinting a fine grained phase density limit for dark matter structures. We explore these effects using high resolution simulations of structure formation in a warm dark matter universe. The Gunn-Tremaine limit is expected to imprint a constant density core at the halo center and we verify this with our simulations which we show preserve Liouville's theorem. The maximum phase space density is conserved and the size of the core is in good agreement with the simple expectations. However, to create a significant core, say about 1 kpc in a dwarf galaxy, one requires a thermal neutrino of 20eV which would erase all structures that form at that mass scale and below. We find that structure formation in these warm dark models occurs top-down on galactic scales where we find the lowest mass haloes collapsing first. The halo mass-concentration mass-redshift formation relations are thus reversed with respect to cold dark matter.

# Simulating the WDM...

$$P(k) = k^n * T^2(k, z) \quad n \sim -1$$

$$k_S \approx \left( \frac{0.3}{\Omega_X} \right)^{0.15} \left( \frac{m_X}{\text{keV}} \right)^{1.15} \text{Mpc}^{-1}$$

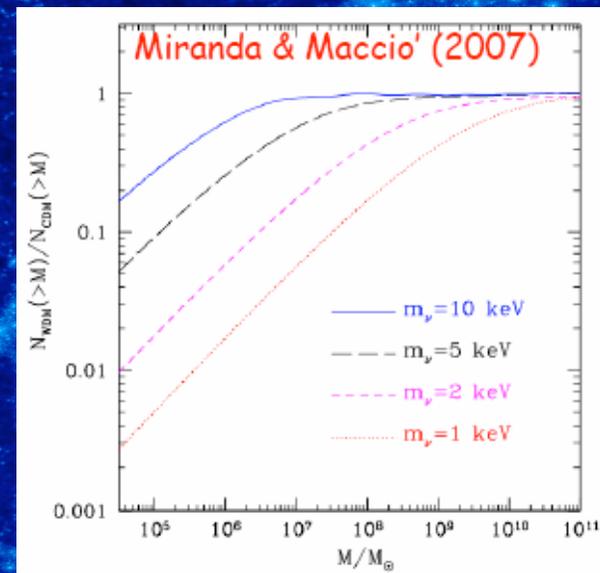

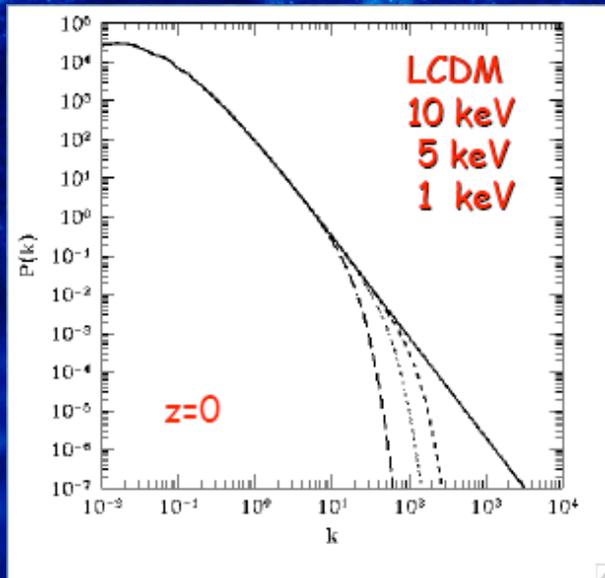

$$T^2(k) = \frac{P^{WDM}}{P^{CDM}} = [1 + (\alpha k)^{2\nu}]^{-10/\nu}$$

$$\alpha = 0.049 \cdot \left( \frac{m_x}{1\text{keV}} \right)^{-1.11} \cdot \left( \frac{\Omega_\nu}{0.25} \right)^{0.11} \cdot \left( \frac{h}{0.7} \right)^{1.22} h^{-1} \text{Mpc}.$$

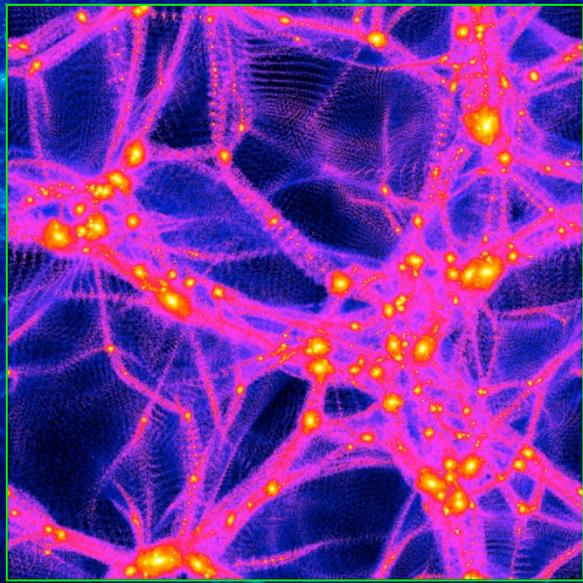

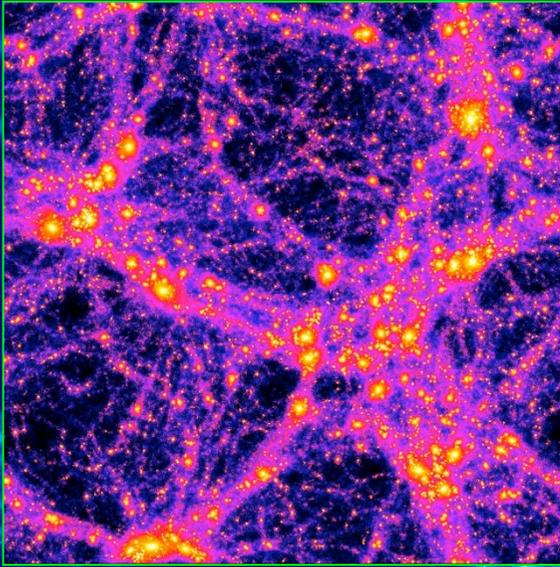

Bode, Turok, and Ostriker (2001)

Viel et. Al 2005

$$\frac{v_0(z)}{1+z} = .012 \left( \frac{\Omega_X}{0.3} \right)^{\frac{1}{3}} \left( \frac{h}{0.65} \right)^{\frac{2}{3}} \left( \frac{1.5}{g_X} \right)^{\frac{1}{3}} \left( \frac{\text{keV}}{m_X} \right)^{\frac{4}{3}} \text{km s}^{-1}$$

## Assumptions in determining the core radius:

- Isothermal spheres
- Liouville - Phase space density (PSD) is conserved
- Pauli exclusion principle
- PSD constant as mixing occurs
- Velocity dispersion in central halo = constant
- Density profile in central halo = constant

## Halo core radii resulting from a phase space limit

$$\rho_0 m_\nu^{-4} (2\pi\sigma^2)^{-3/2}$$

Maximum phase space density for a Maxwellian velocity distribution – Tremaine & Gunn (1979)

$$r_c^2 = 9\sigma^2 / 4\pi G\rho_0.$$

The core radius

$$m_\nu > (100\text{eV}) \left( \frac{100\text{ km s}^{-1}}{\sigma} \right)^{-1/4} \left( \frac{1\text{ kpc}}{r_c} \right)^{1/4} g_\nu^{-1/4}.$$

Minimum mass for neutrinos

$$Q_{\max} = 5 \times 10^{-4} \beta \left( \frac{g}{2} \right) \left( \frac{m_x}{1\text{keV}} \right)^4 M_\odot \text{pc}^{-3} (\text{km s}^{-1})^{-3}$$

Maximum phase space density

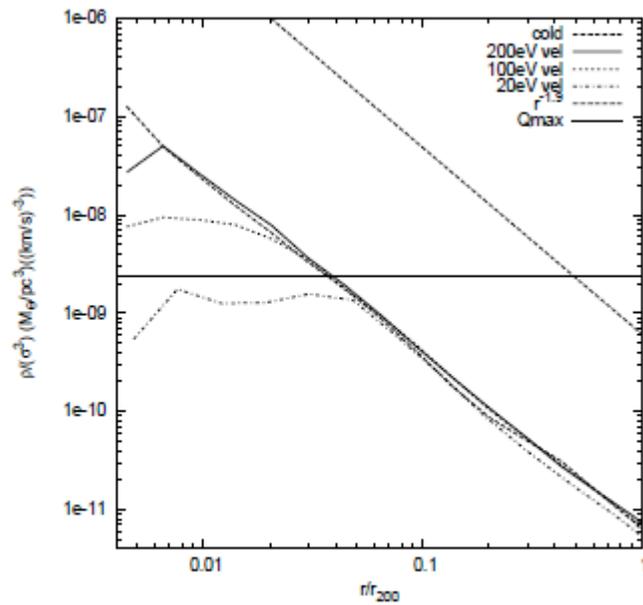

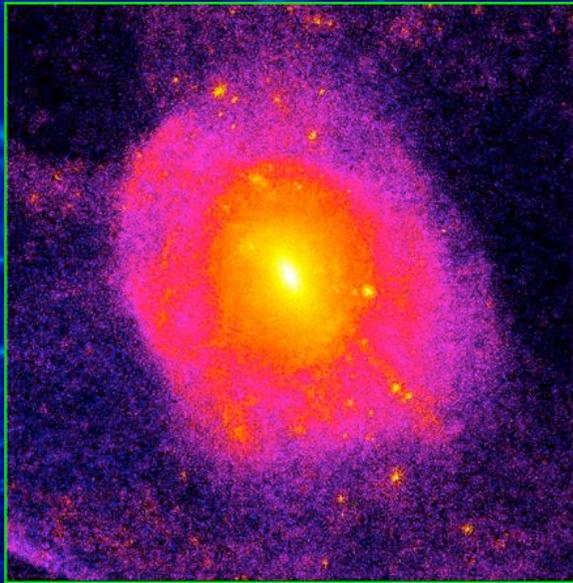

$$Q_0 = \frac{\rho}{\sigma^3} = \rho_{\text{crit}} \Omega \left( \frac{m_\nu c^2}{KTc} \right)^3$$

PSD in our simulations, for a constant density in the initial conditions

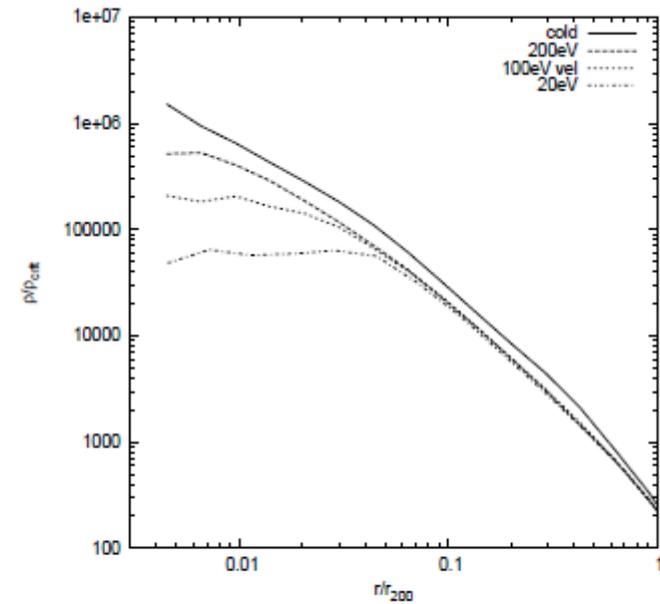

$$Q_0 = 3 \times 10^{-4} M_\odot \text{pc}^{-3} (\text{km/s})^{-3} \left( \frac{m_x}{1\text{keV}} \right)^3$$

$$r_{c,\min}^2 = \frac{\sqrt{3}}{4\pi G Q_0} \frac{1}{\langle \sigma^2 \rangle^{1/2}}$$

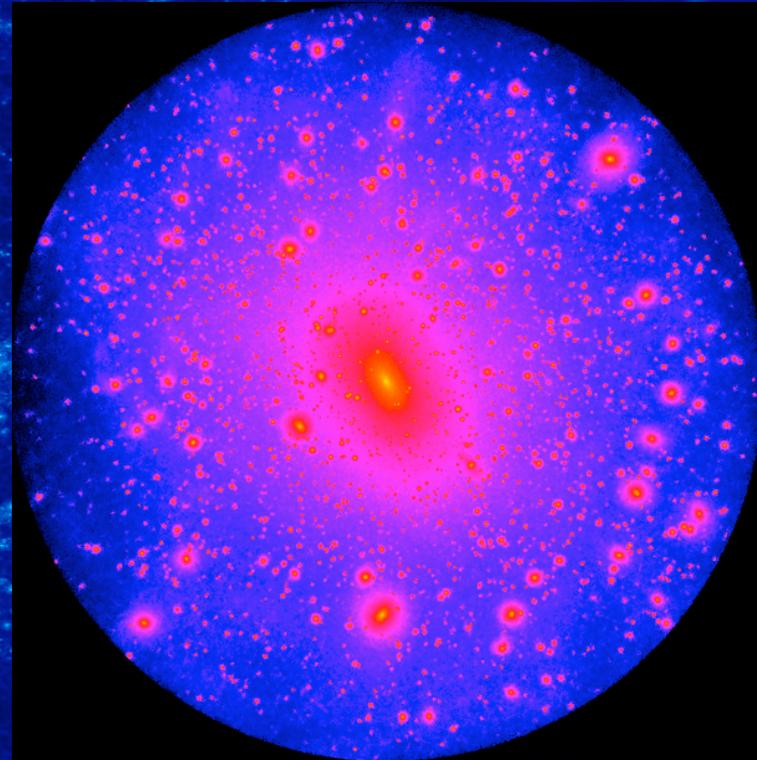

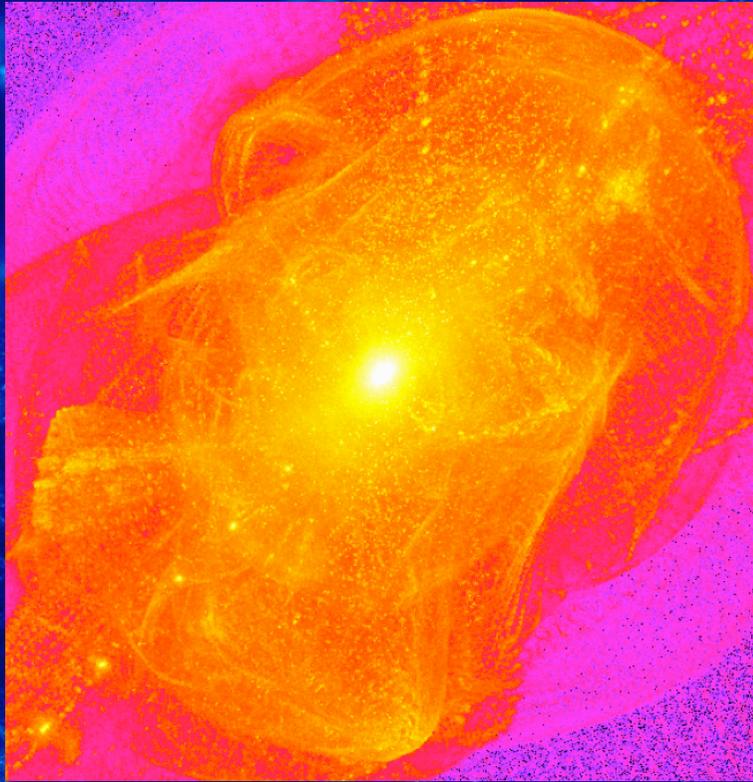

The core radius

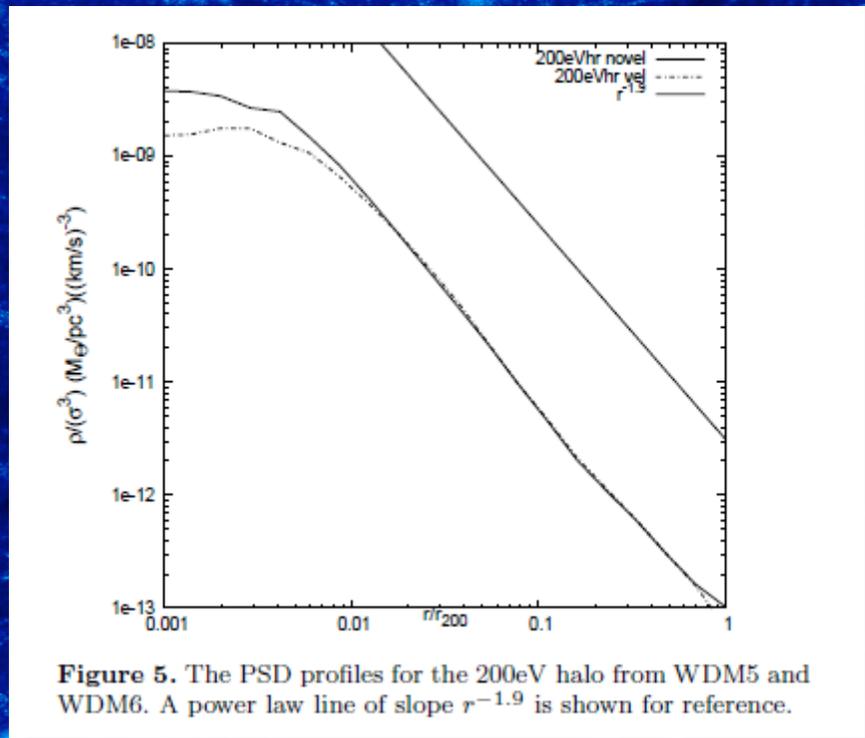

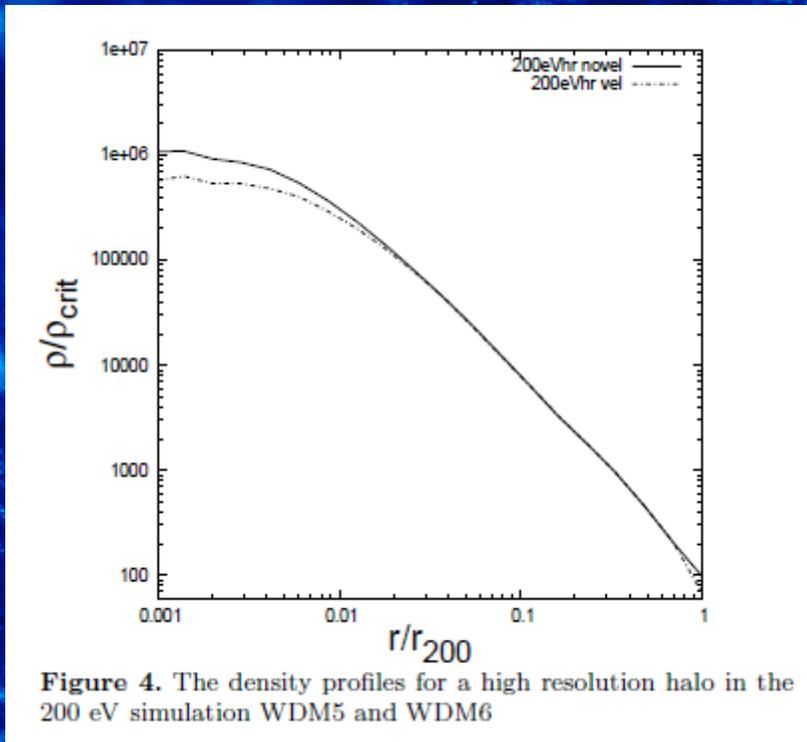

**Figure 3.** “Phase-space density” (PSD) profiles of the same haloes shown in Figure 1, calculated using  $\rho/\sigma^3$ .

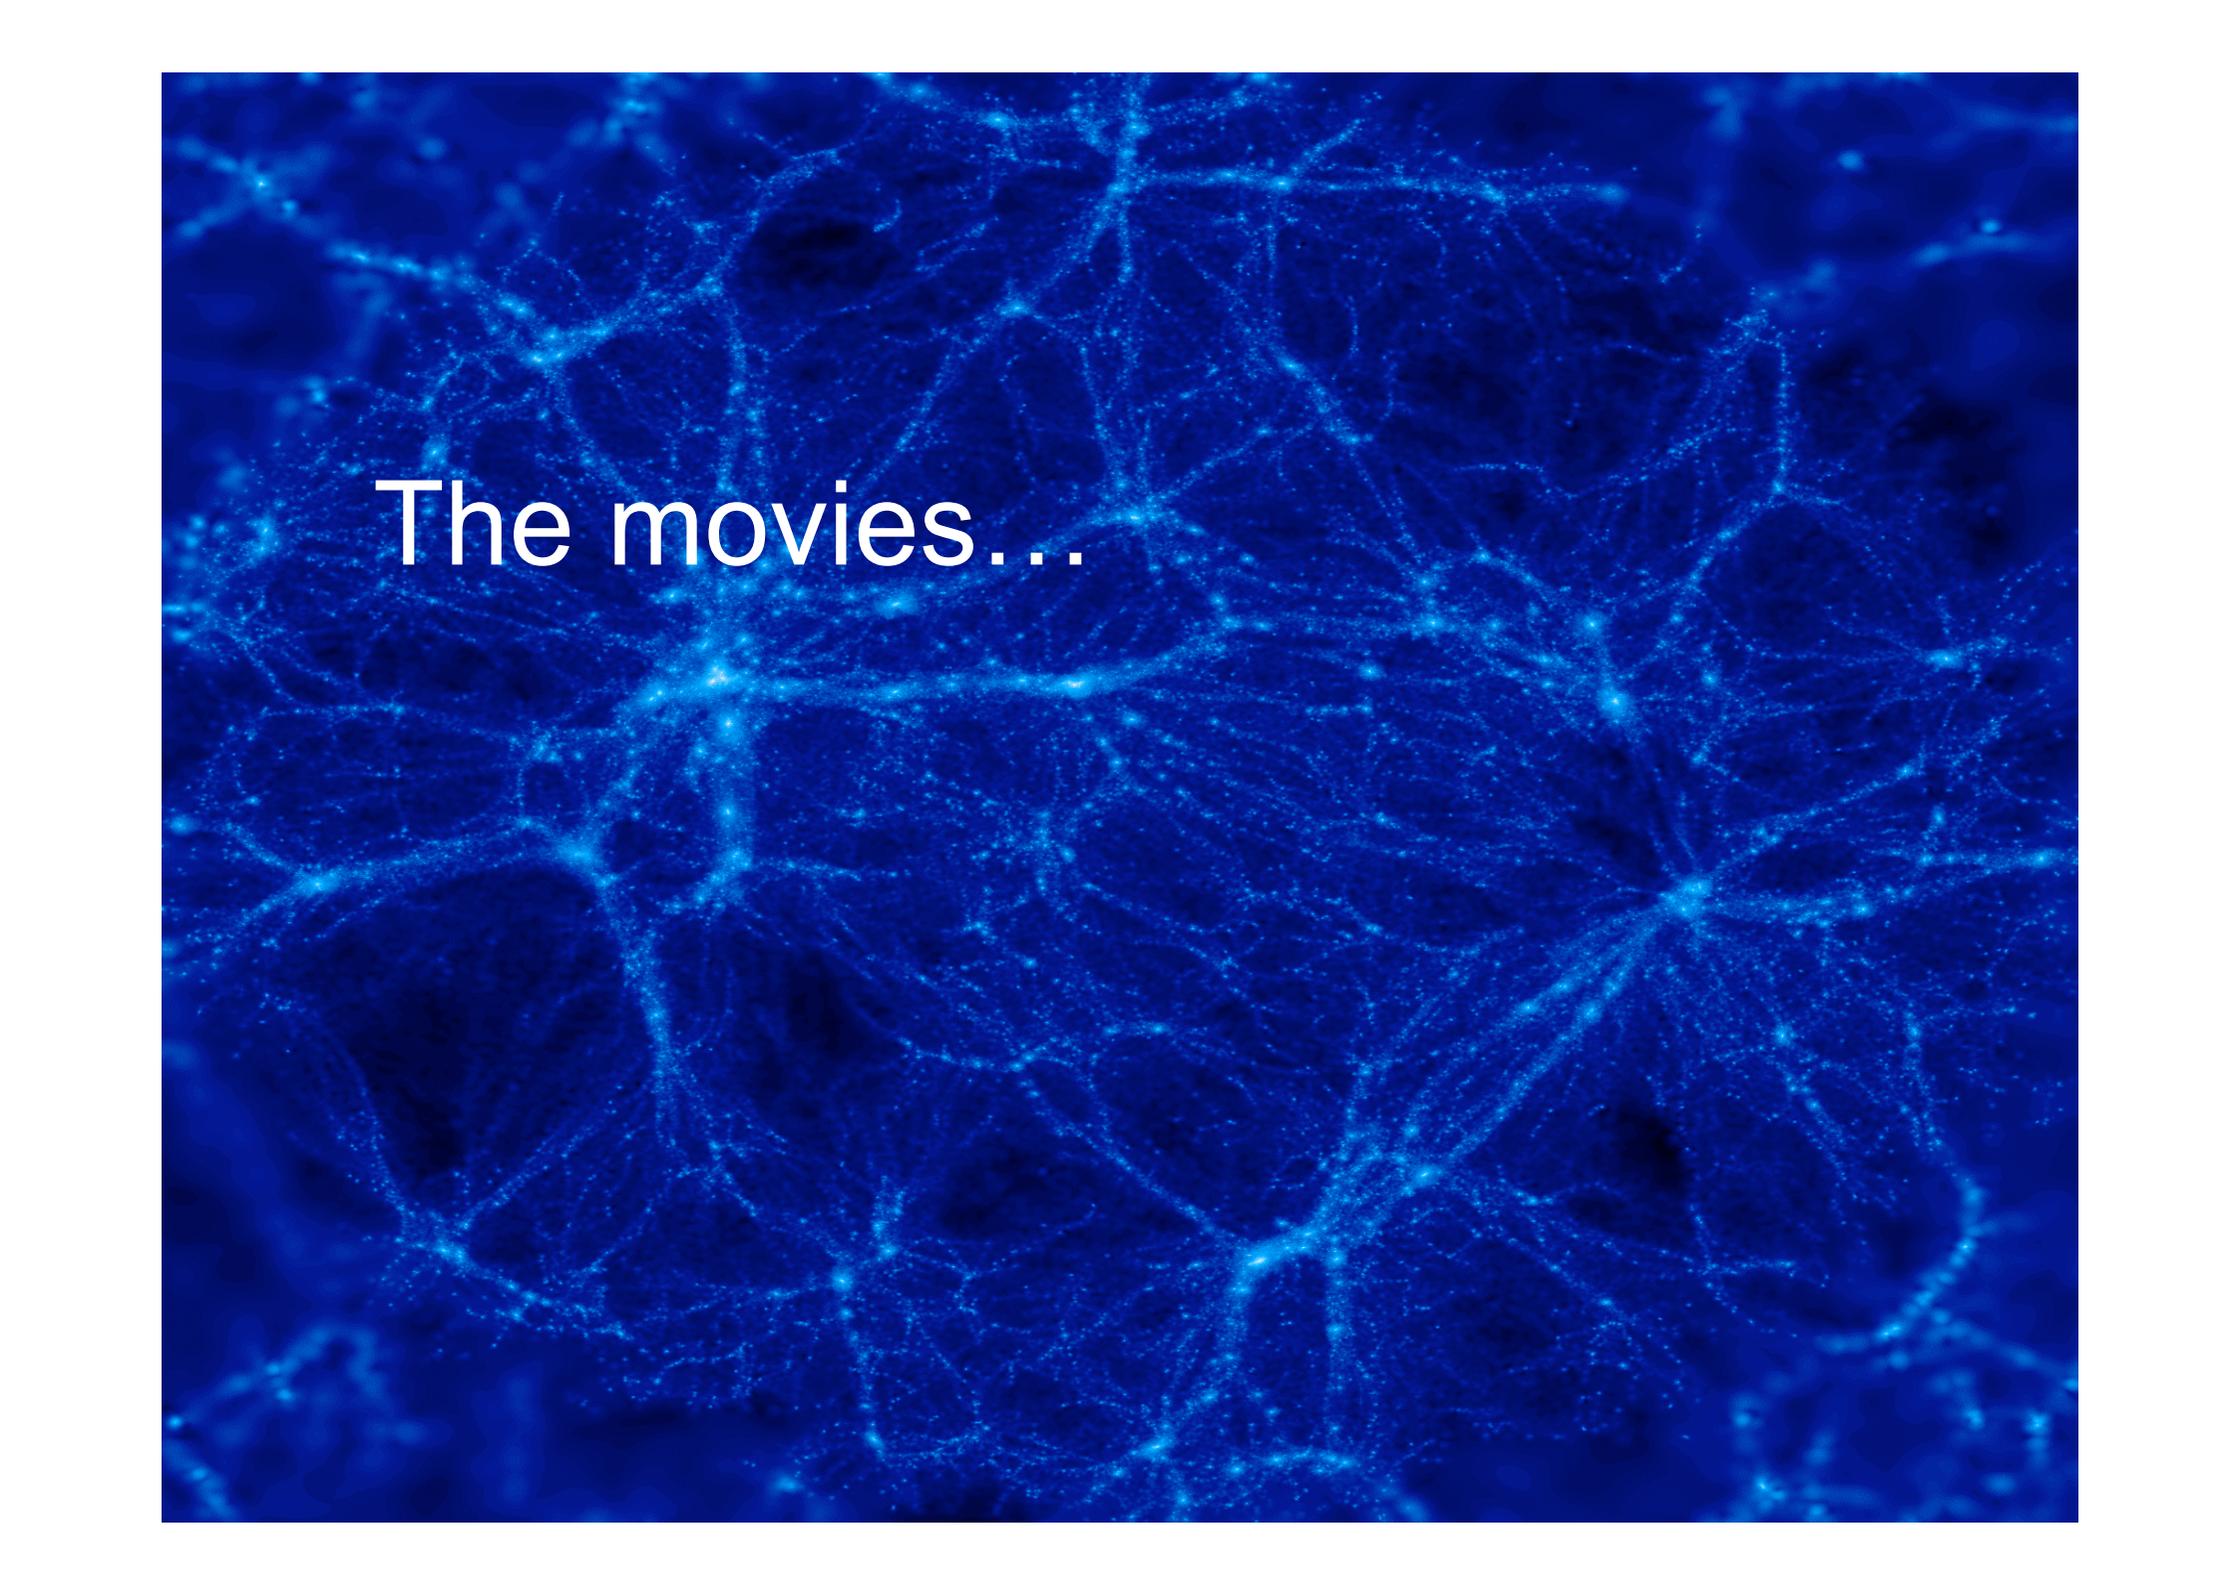

**Figure 2.** The spherically averaged density profiles for CDM, WDM1, WDM2 & WDM3 haloes. The resolution limit is at approximately 0.5% of the virial radius (the softening radii are a 0.26% of the virialized radius).

	Number of part.	$r_{vir}$ [kpc]	mass p. part. [ $M_{\odot}$ ]	boxsize [Mpc]
$m < 200\text{eV}$	18 mil.	630	$10^5$	42.5
$m > 2\text{keV}$	50 mil.	200	$10^7$	40

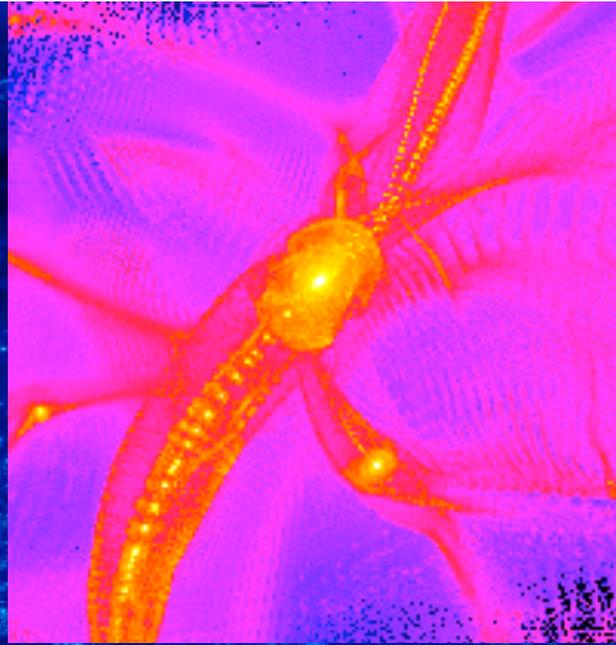

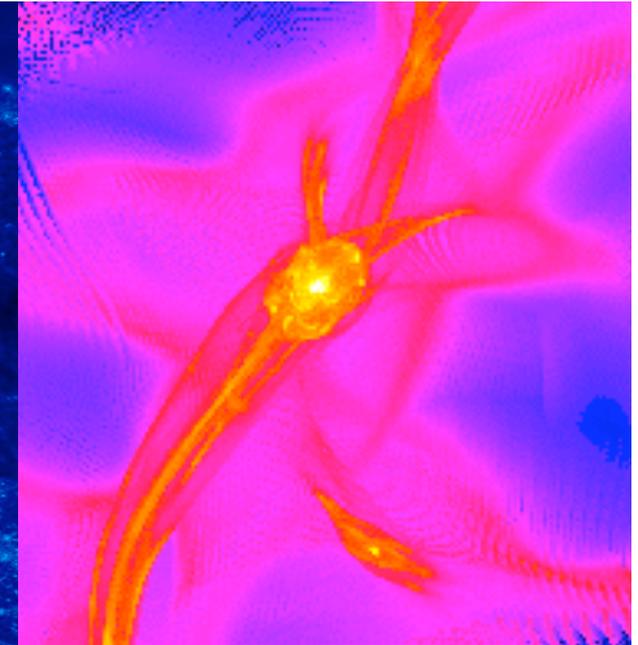

The movies...

"Low" resolution

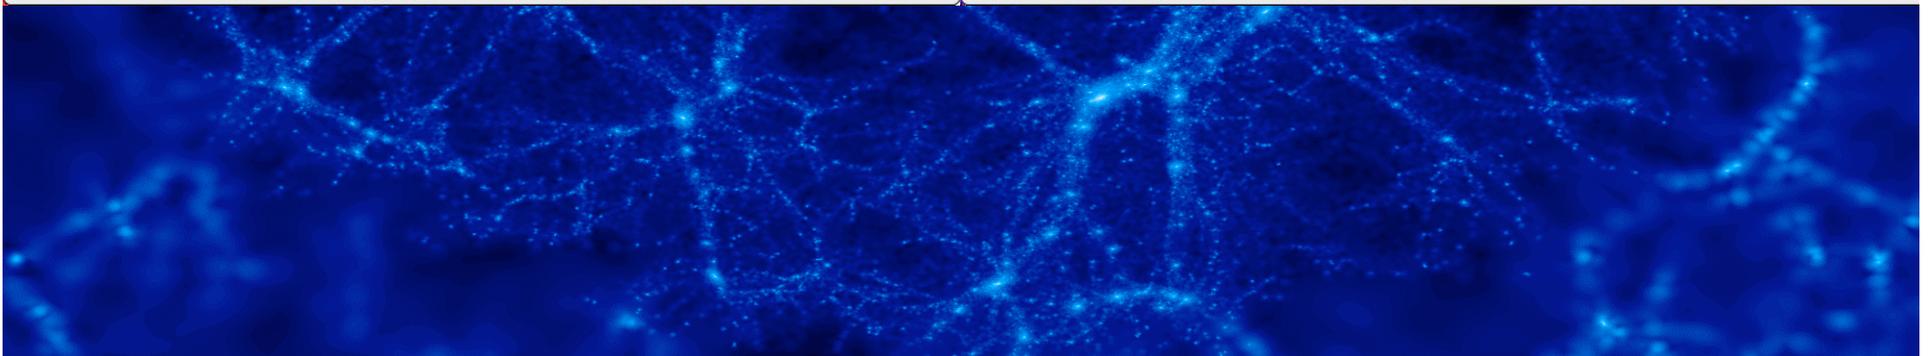

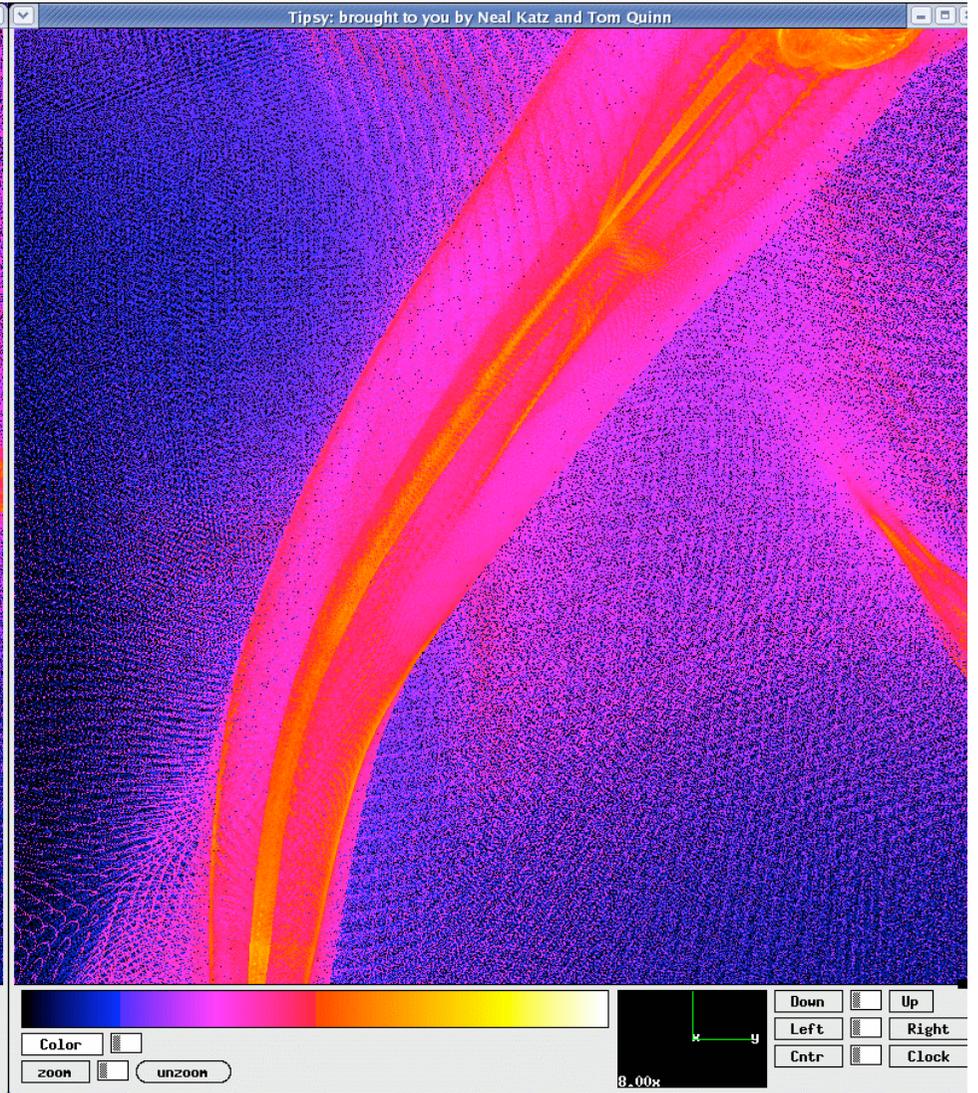

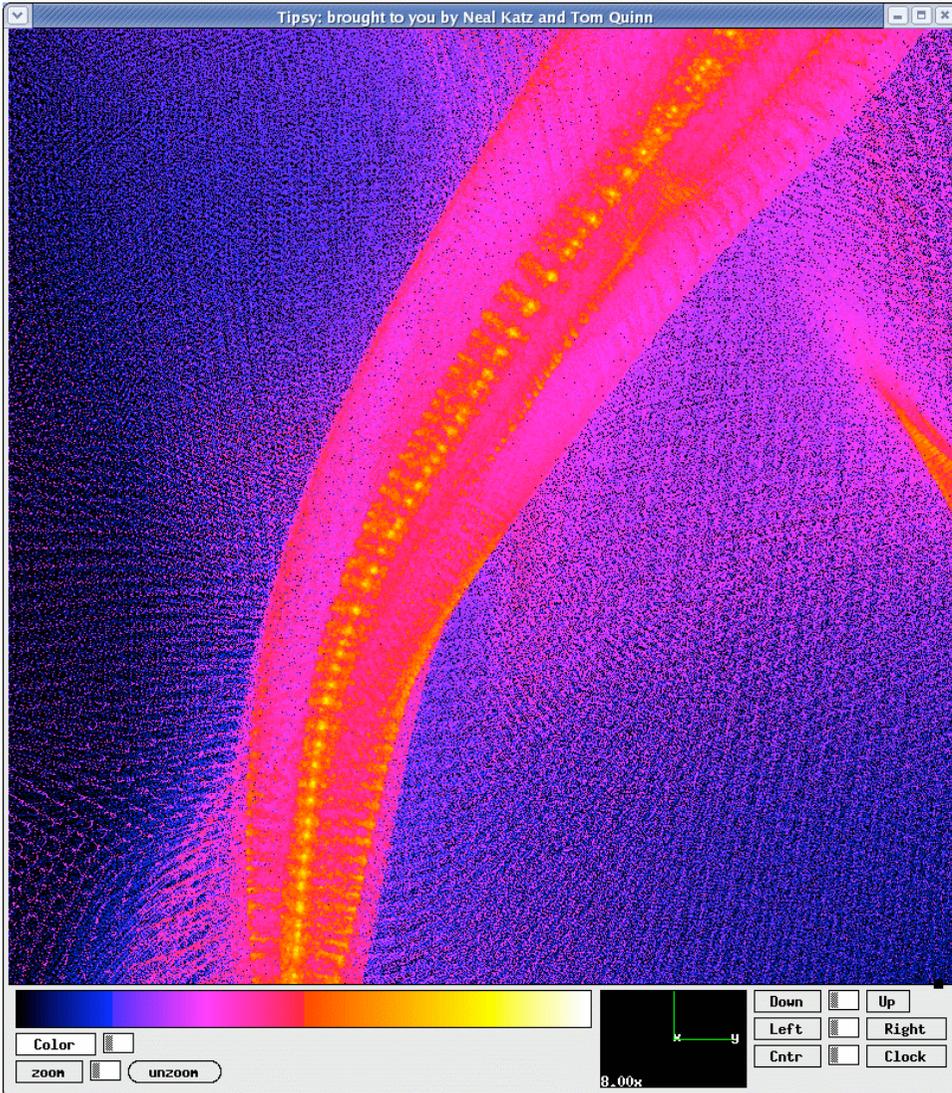

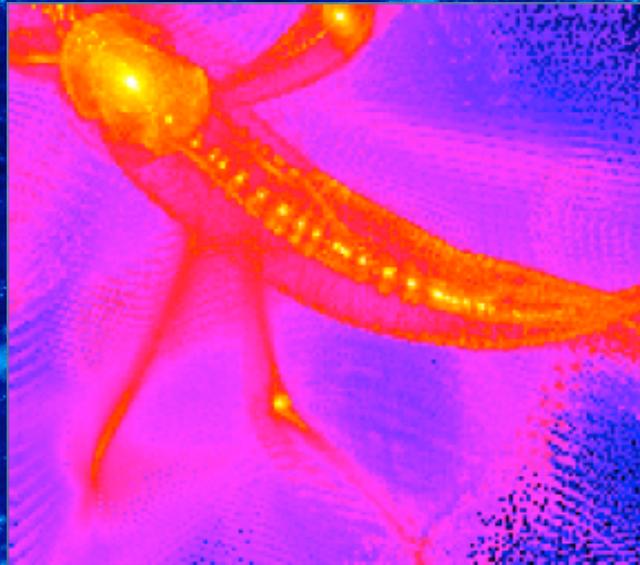

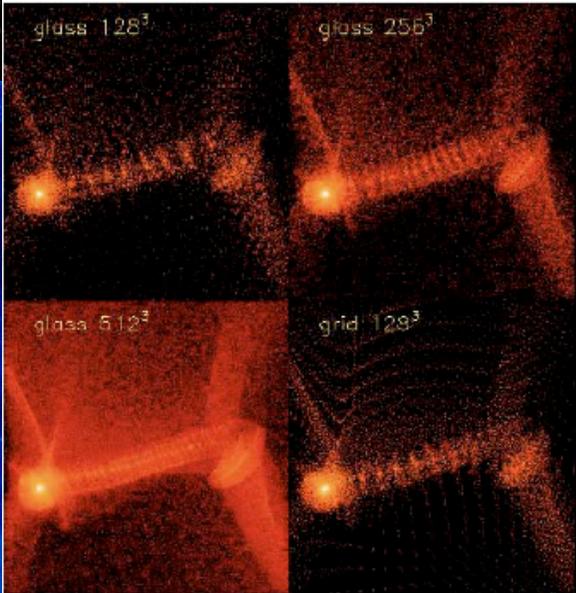

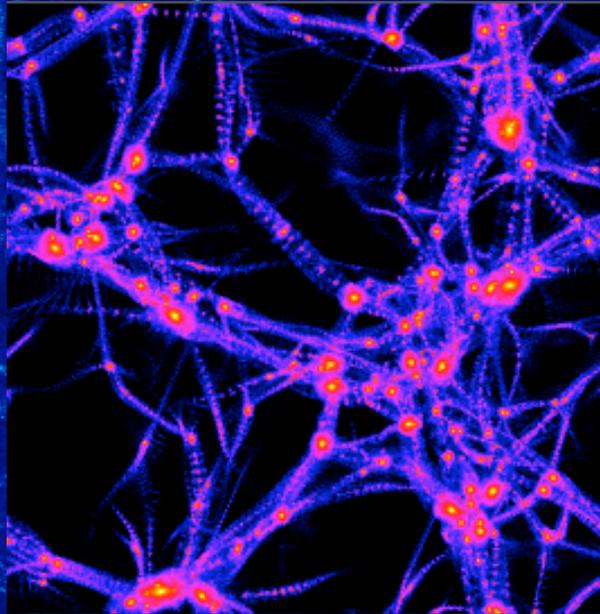

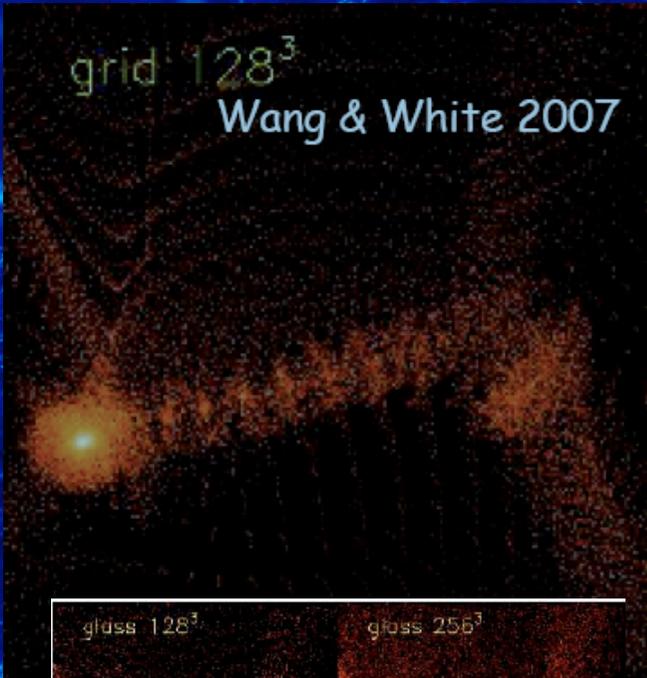

"High" resolution

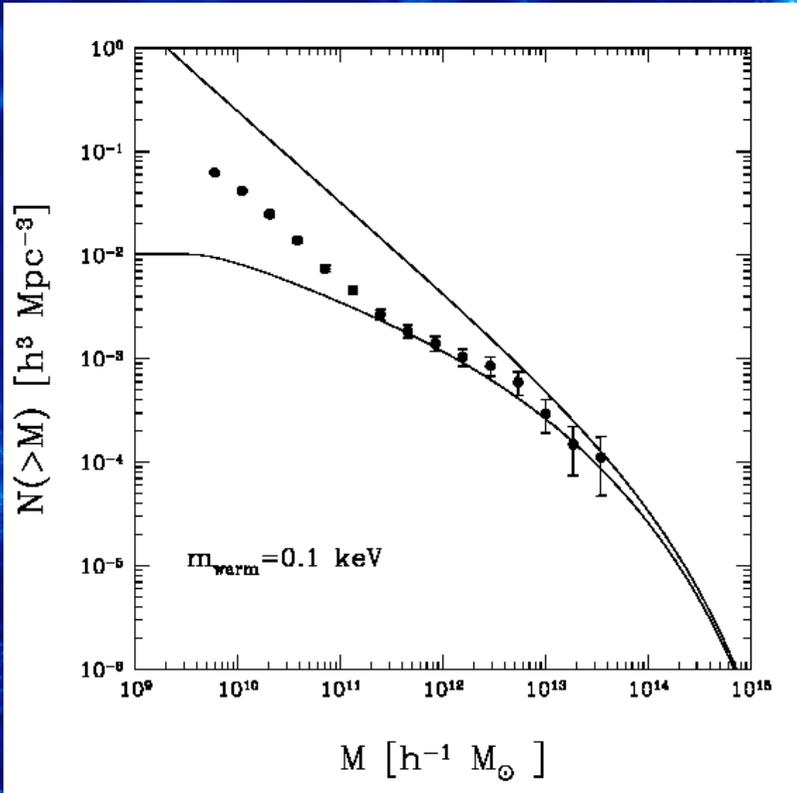

"High" resolution

WDM  $N_p > 50$

CDM & WDM  $N_p > 500$

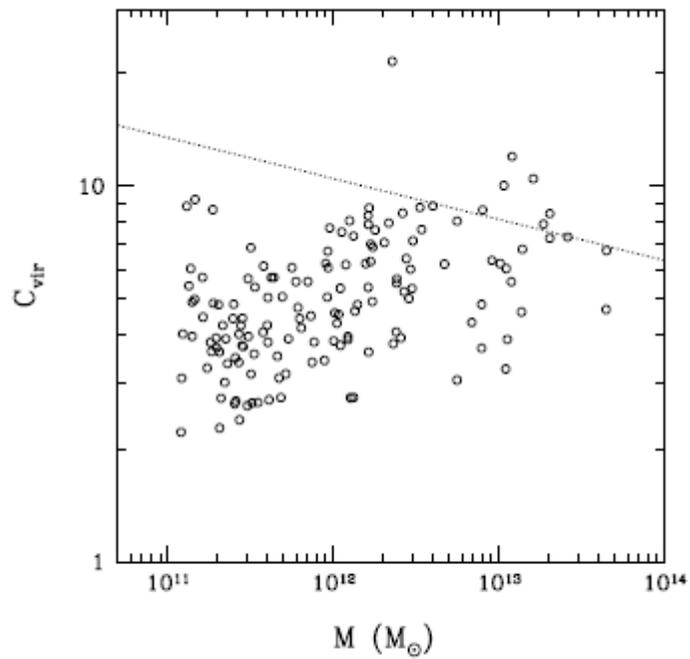

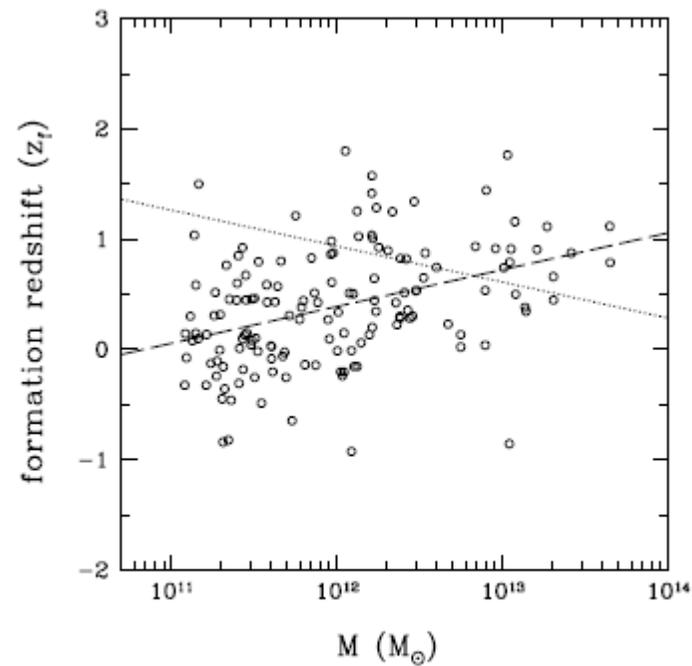

Mildly non-linear regions at  $z=3$  in CDM and WDM (200eV)  
i.e. overdensities between 1 and 5 w.r.t. mean

Virialised regions at  $z=3$  in CDM and WDM (200ev)  
i.e. overdensities higher than 100 w.r.t. mean

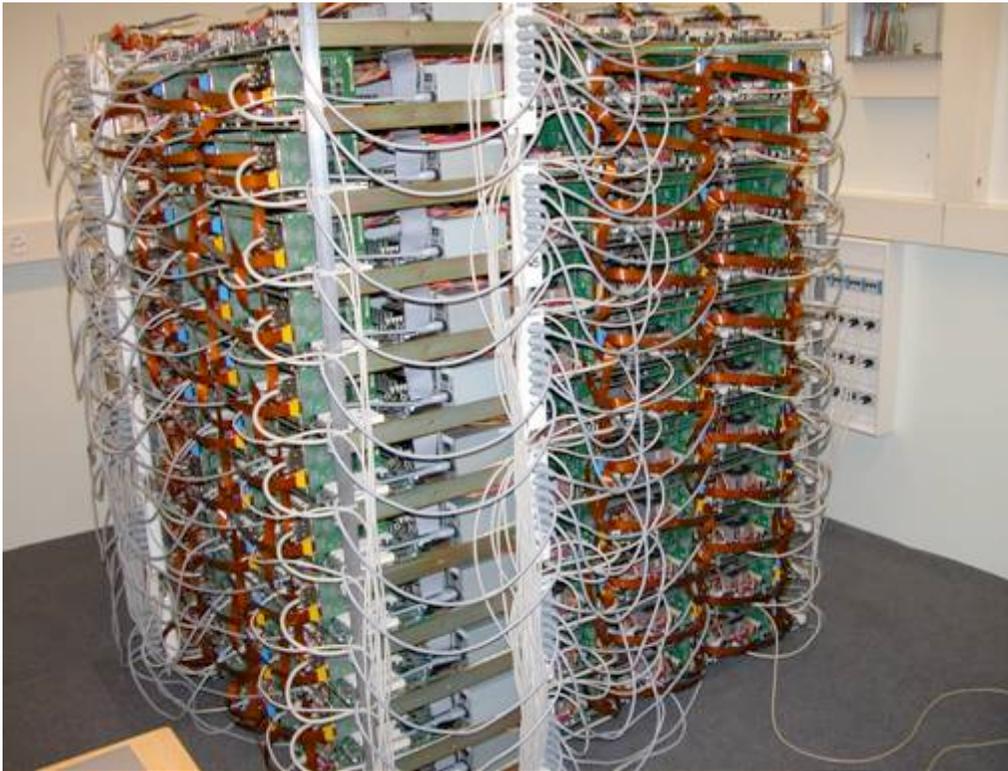

**Figure 7.** The mass concentration relation for haloes in the WDM6 simulation. The dotted line shows results for the  $\Lambda$ CDM model from Macciò et al. (2007).

**Figure 8.** The relation between the formation redshift and mass of haloes in the WDM6 simulation. The dashed line is a fit to the WDM data, the dotted line shows the expected behaviour in a  $\Lambda$ CDM scenario.

# CONCLUSIONS

- The finite initial fine grained PSD is also a maximum of coarse grained PSD.
- The turn over in PSD results in constant density core with characteristic size.
- Formation of haloes in WDM models differs from CDM. Large haloes form first from the fragmentation of intersecting filaments
- The concentration – mass relation for WDM haloes is reversed with respect to that found for CDM
- Spurious fragmentation below the free streaming scale hard to overcome – in case of infinite resolution a filament collapses into a two dimensional line
- If the primordial velocities are large enough to produce a significant core in dwarf galaxies, then the free streaming erases all perturbations on that scale so that the haloes can not form.
- Warm dark matter haloes contain visible caustics and shells.

## zBox2 (2006)

500 quad Opteron 852's, 580Gb memory, 65Tb disk, 3d-SCI low latency network.

## zBox1: (Stadel & Moore 2002)

288 AMD MP2200+ processors, 144 Gigs ram

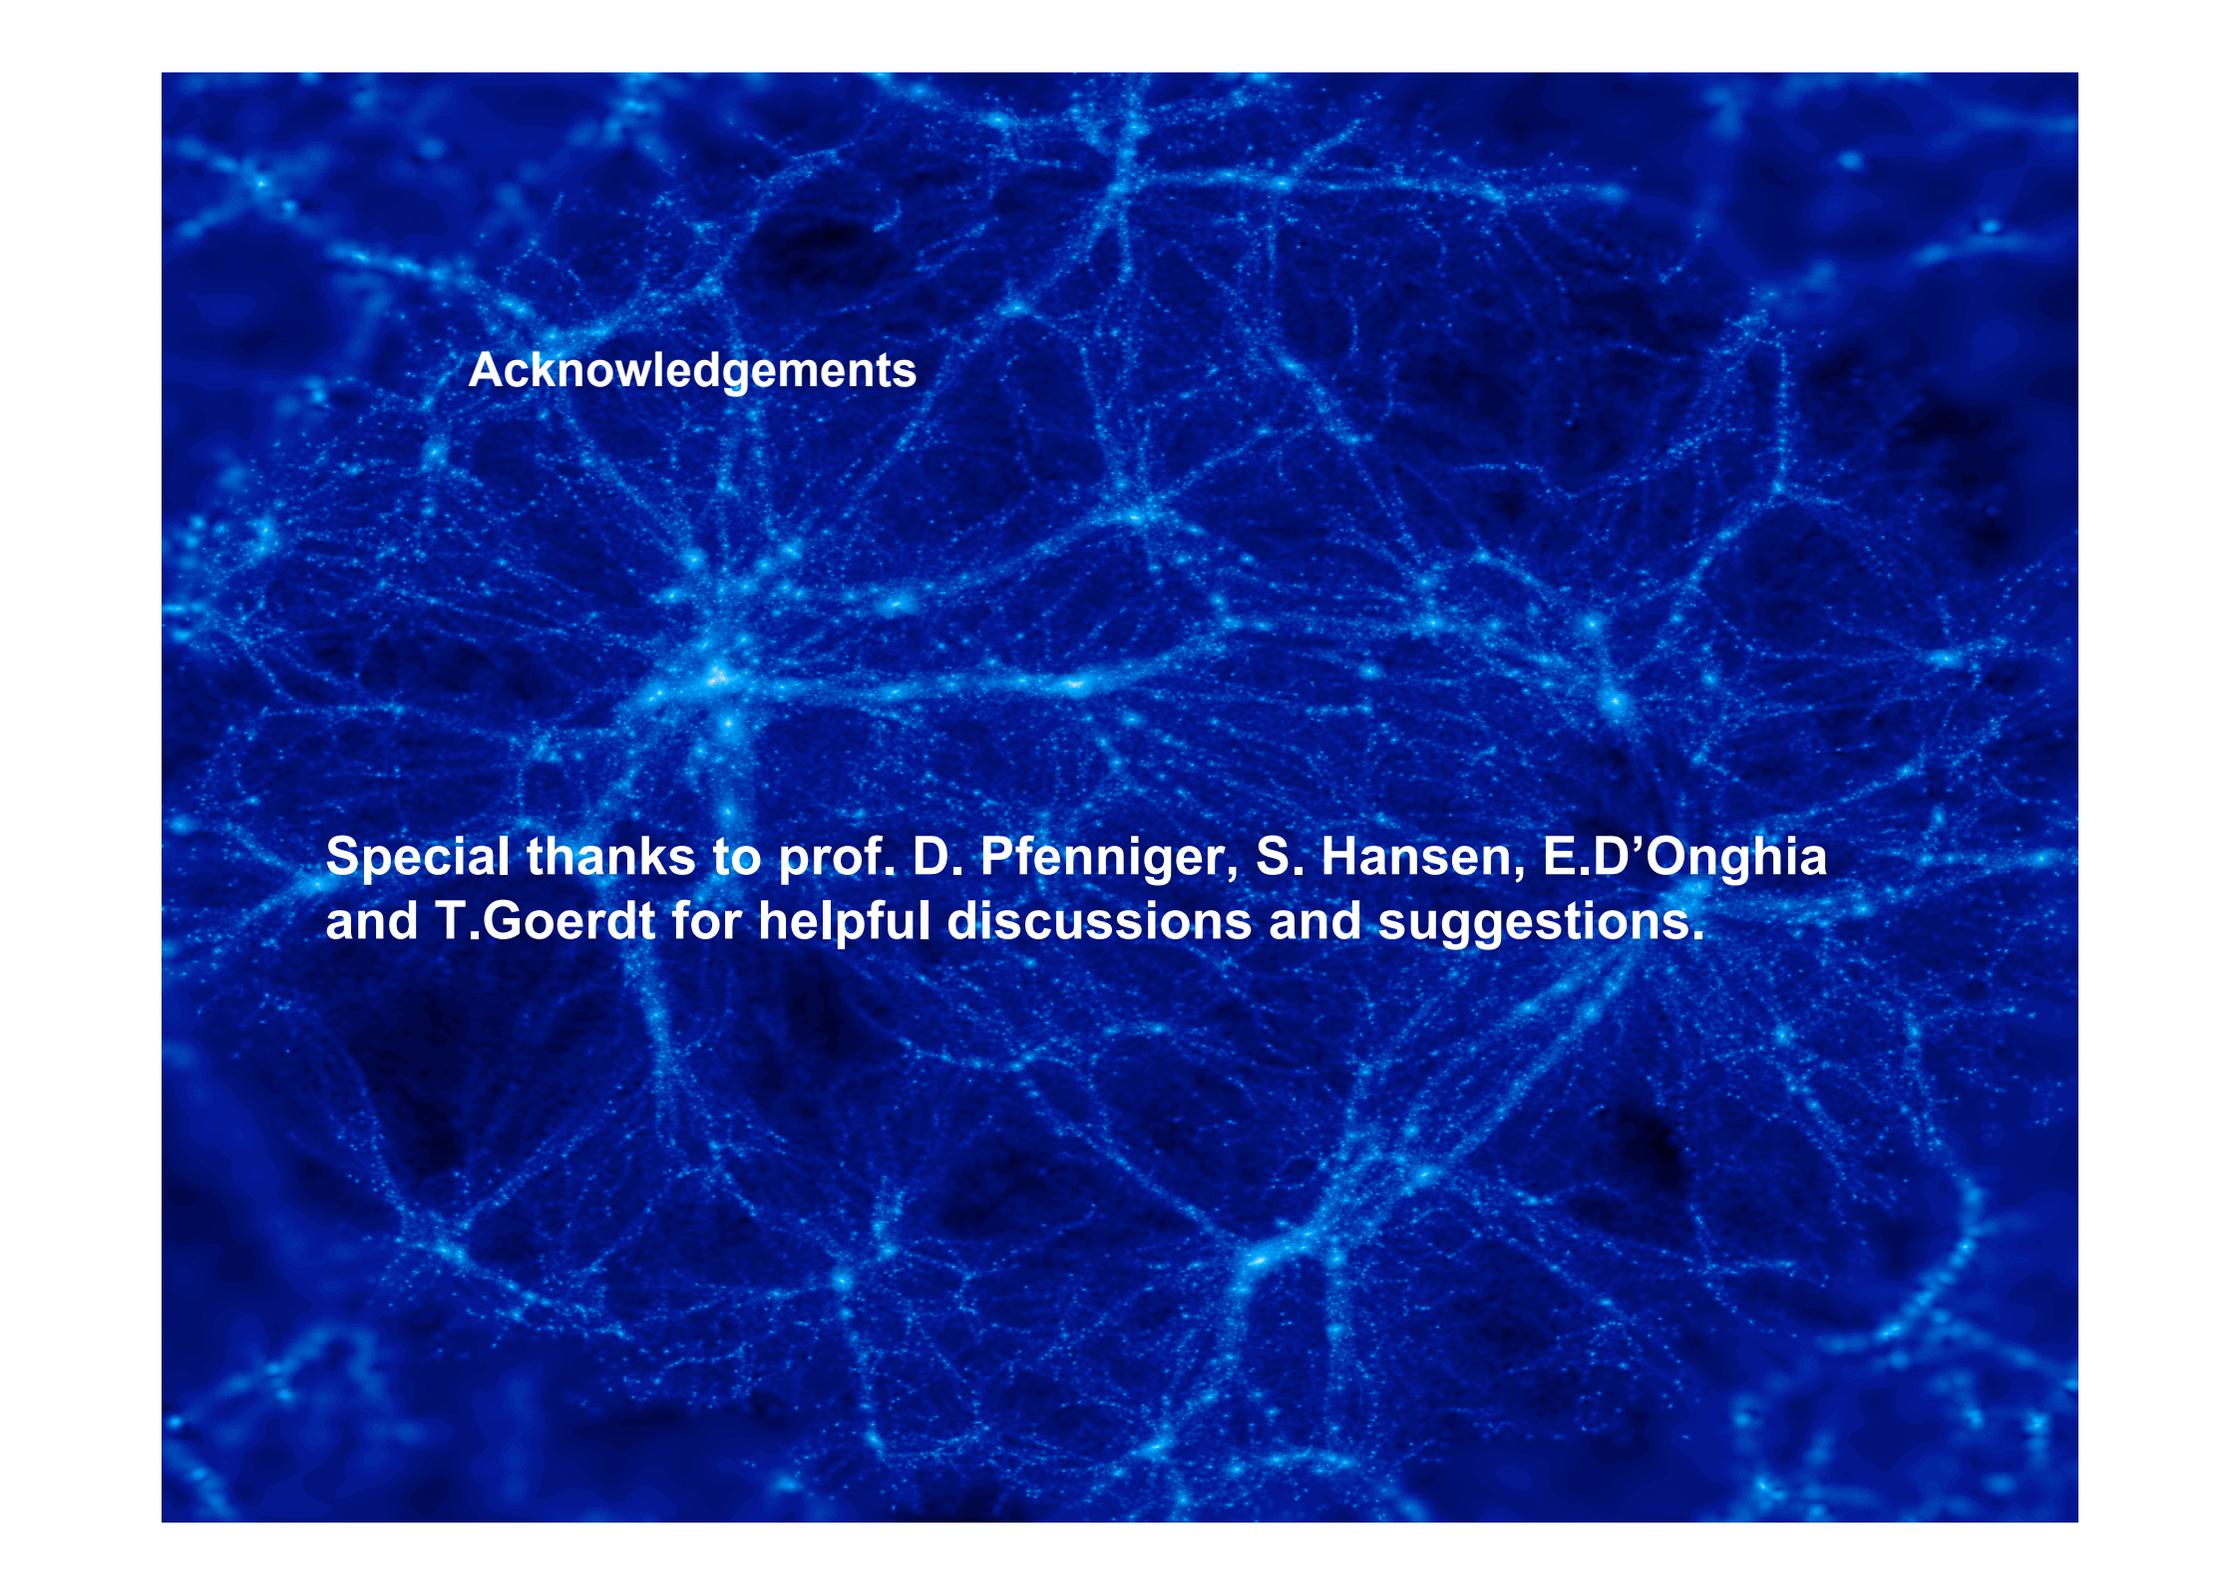

Compact, easy to cool and maintain

Very fast Dolphin/SCI interconnects - 4 Gbit/s, microsecond latency

A teraflop supercomputer for \$500,000

Roughly one cubic meter, one ton and requires 40 kilowatts of power
